INTRODUCTION

Why this guide exists and how to use it

Here's the thing nobody tells you about getting faster after 40. It's not that your body can't do it. It's that everything you're reading online — the Reddit threads, the forum advice, the generic training plans — was written for a 25-year-old with no job, no family, and 20 hours a week to ride.

You're not that person. You've got a career, responsibilities, and maybe 8 to 12 hours a week on the bike if you're lucky. And yet you refuse to accept that your best riding is behind you. Good. Because it isn't.

I've spent the last five years sitting across from the coaches behind Grand Tour wins, Olympic medals, and World Championship jerseys. Dan Lorang, who coached Tadej Pogačar and Jonas Vingegaard. Professor Stephen Seiler, the man who proved the polarised training model. Dr David Dunne, whose evidence-based approach to sports science has changed how we think about recovery and adaptation.

I asked every single one of them the same question: **what would you actually prescribe to a serious amateur cyclist over 40?**

This report is their answer. Distilled across five pillars — Coaching, Nutrition, Strength & Conditioning, Recovery, and Community — and written for the rider with a real life, real constraints, and a quiet refusal to settle.

"The science is clear: age-related decline in cycling performance is far slower than most people assume. The problem isn't biology. It's methodology."

— Professor Stephen Seiler

I built this guide because I needed it myself. I was the rider stuck in the grey zone, training hard but not getting faster, eating less but not getting leaner, doing everything the internet told me to do and wondering why none of it was working.

Then I started asking the right people the right questions. Not fitness influencers. Not weekend warriors with a blog. The people who actually coach the best riders in the world. And what they told me changed everything.

HOW TO USE THIS GUIDE

Each section pairs the science with a specific framework you can apply this week. Not next month. Not when you've bought new kit. This week. Every claim is grounded in named sources — real coaches, real studies, real results. No vague advice. No motivational fluff.

Read it in order the first time. After that, jump to whichever pillar needs the most attention. Most riders will find that fixing one pillar unlocks progress in all the others. That's the whole point of the system.

At the end of each chapter you'll find a framework — a specific, actionable protocol you can start using immediately. These aren't vague principles. They're the same structures that World Tour coaches use, adapted for riders with 8 to 12 hours a week.

Let's get into it.

02

THE FIVE-PILLAR SYSTEM

An overview of the framework
that changed everything

Before we dive into each pillar, here's the single most important thing to understand: **these five pillars don't work in isolation.** Coaching without recovery breaks you down. Nutrition without training structure wastes your effort. Strength work without community accountability dies after three weeks.

The system works because the pillars reinforce each other. Fix your nutrition and your training quality improves. Improve your recovery and your body actually adapts to the training. Add accountability and you stop skipping sessions when life gets busy.

1

COACHING

The polarised training model, periodisation for real life, and the specific sessions World Tour coaches prescribe for time-limited athletes. Expert insight from Dan Lorang and Professor Stephen Seiler.

2

NUTRITION

Why calorie restriction is making you slower and fatter. The fuelling-first approach that builds performance and changes body composition as a byproduct. Expert insight from Dr David Dunne.

3

STRENGTH & CONDITIONING

The exercises to avoid after 40 and the five movements adapted from elite cycling programmes. No heavy barbell work. No injury risk. Maximum transfer to the bike.

4

RECOVERY

Sleep science, stress management, HRV tracking, and the adaptation protocol. Why what worked at 30 doesn't work now — and what to do instead.

5

COMMUNITY

Why the lone wolf cyclist always plateaus. The craft of being a cyclist, the science of group training effects, and what accountability actually looks like for adults with careers.

Each chapter ends with a framework — a specific protocol you can implement this week. The frameworks are designed to work together, but each one delivers value on its own. Start with the pillar that feels most broken. Fix that first. Then layer in the rest.

"You don't need to fix everything at once. Find the one thing that's leaking the most performance, plug it, and the rest starts to fall into place. Small little leaks that add up to minutes on every meaningful ascent."

— Anthony Walsh, Roadman Cycling Podcast

03

COACHING

The polarised model, periodisation, and the sessions that actually work

Here's what nobody tells you about pro cyclists. They spend about 80% of their time riding at a pace so slow that recreational riders would be able to ride with them. Maybe some recreational riders would ride past them on the bike path.

That's not a typo. The best riders on the planet ride easy most of the time. And then, when they go hard, they go properly hard. This is the polarised training model, and Professor Stephen Seiler has spent two decades proving why it works.

THE GREY ZONE: WHERE MOST AMATEURS GET STUCK

The single biggest mistake age-group cyclists make is riding in what coaches call the grey zone. You're riding about 50% too hard when you think you're riding easy. Too hard to be truly easy, too easy to be truly hard. The result? You accumulate fatigue without building fitness. Same sessions, same errors, same effort — and you wonder why the power numbers won't move.

When I had Dan Lorang on the podcast, he was blunt about it. The riders he coaches — including Pogačar — have their easy days prescribed with strict power ceilings. If they go above it, they hear about it. That's how seriously World Tour teams take this.

DAN LORANG

Head of Performance, Red Bull—Bora—Hansgrohe — Coached Pogačar & Vingegaard

"The biggest gains for time-limited athletes come from discipline on easy days, not from adding more intensity. If you can't control your Zone 2, you can't control your season."

THE 80/20 INTENSITY DISTRIBUTION

Seiler's research is unambiguous. The optimal training intensity distribution for endurance athletes is approximately 80% low intensity (Zone 1—2) and 20% high intensity (Zone 4—5). The middle zone — Zone 3, tempo, sweetspot — should represent a small fraction of total training time.

For a rider training 10 hours a week, that means roughly 8 hours should be genuinely easy. Not sort of easy. Not easy for me. Easy as in you could hold a full conversation without pausing for breath. The remaining 2 hours should be structured, specific, and hard enough to drive adaptation.

Here's the good news: this model was designed for exactly your situation. It doesn't require 25 hours a week. It requires discipline and structure with whatever hours you have.

PERIODISATION FOR REAL LIFE

The second mistake most self-coached riders make is doing the same training week after week without structure, progression, or recovery phases. No periodisation. No plan for when to push and when to absorb.

A properly periodised season for a time-limited rider over 40 typically follows a pattern: a base-building phase focused on aerobic development (longer Zone 2 work), a build phase where intensity increases, a specificity phase targeting your goal event, and structured recovery weeks every third or fourth week.

PROFESSOR STEPHEN SEILER

Exercise Physiologist — Pioneer of Polarised Training Research

“Periodisation isn’t about complicated spreadsheets. It’s about asking one question every week: am I absorbing the training I’ve done? If the answer is no, you need to back off before you push again. This becomes more important, not less, after 40.”

LOW-CADENCE TORQUE INTERVALS: THE MOST UNDERRATED SESSION

For years, the cycling internet told you low-cadence work was a waste of time. The coaches knew otherwise. They kept prescribing these sessions anyway and waited for the science to catch up.

In 2024, the science finally did. A study by Raphael and Paulina Habis, published in PLOS ONE, compared low-cadence interval training against freely chosen cadence work. The low-cadence group improved VO_2max by 8.7% versus 4.6%. Maximum aerobic power went up 8.1% versus 3%.

Why does it work? Three reasons. First, it forces your fast-twitch (Type 2) muscle fibres to work at aerobic intensities, causing them to develop more mitochondria. Second, it builds new neuromuscular pathways — your brain learns to recruit more muscle fibres per pedal stroke. Third, it expands your aerobic engine without adding training volume. For time-limited riders, that’s massive.

YOUR COACHING FRAMEWORK: WEEKLY TRAINING ARCHITECTURE

- 2–3 Zone 2 rides (60–90 min) — genuinely easy, power-capped
- 1 structured interval session (VO_2max or threshold)
- 1 low-cadence torque session (4x4 min at 40–60 RPM, RPE 7/10)
- 1–2 rest days (not optional — see Recovery chapter)
- Every 3rd week: reduce volume and intensity by 30–40%

THE FIVE MISTAKES SELF-COACHED RIDERS MAKE

1

NO PERIODISATION

Doing the same training week after week without structure, progression, or recovery phases. Your body adapts to a stimulus within 4–6 weeks. If you don’t change the stimulus, you stop adapting.

2

IGNORING RECOVERY

Training through fatigue, not respecting rest days, treating every ride as a chance to push. After 40, this approach doesn't just stall progress — it causes regression.

3

WRONG METRICS OBSESSION

Obsessing over TSS or weekly volume rather than quality indicators. A 10-hour week of grey-zone riding delivers less adaptation than 7 hours of properly polarised training.

4

NO ACCOUNTABILITY

Training alone without a feedback loop. No one to tell you when you're overcooked or when your pacing is off. The lone wolf problem (more on this in the Community chapter).

5

INTENSITY WITHOUT STRUCTURE

Adding hard sessions without a plan for when they fit in the week, how they interact with each other, or when to absorb the work. Random intensity creates random results.

Here's the good news: every one of these is fixable. The coaching framework above addresses all five. It's not about training more. It's about training with structure, specificity, and the discipline to ride easy when the plan says easy.

04

NUTRITION

Why eat-less-ride-more is making you slower
— and what to do instead

The cycling internet is going to tell you that weight loss is simple. Calories in versus calories out. Burn more than you eat. Ride more. Eat less. This advice is so outdated. It's not just incomplete. It's actually making you fatter.

I lost 7kg in 12 weeks. I went from 86 to 79kg. And I did it while eating more food than I've ever eaten in my entire life. My power didn't drop. My energy went up. I stopped craving junk food at 9pm. And I didn't download MyFitnessPal once.

What I didn't do was skip meals. What I didn't do was go on fasted rides and end up bonking 60km from home absolutely hating my life. What I didn't do was restrict, count, and white-knuckle my way through another failed diet. I didn't do any of that.

THE FUELLING-FIRST APPROACH

The paradigm shift is simple: eat to fuel performance, not restrict to lose weight. When you fuel properly — the right foods, at the right times, in the right quantities — your body composition changes as a byproduct. You lose fat because your metabolism is working, not because you're starving it.

Dr David Dunne's research backs this up. The evidence is clear that chronic energy deficit — especially in masters athletes — leads to hormonal disruption, muscle loss, impaired recovery, and paradoxically, increased fat storage. Your body thinks it's in a famine and responds accordingly.

DR DAVID DUNNE

Sports Scientist — Evidence-Based Performance

"The masters cyclist who chronically under-fuels is fighting their own biology. After 40, your hormonal response to energy deficit becomes more aggressive. You lose muscle faster, recover slower, and store fat more efficiently. The solution isn't less food. It's better food, timed correctly."

IN-RIDE NUTRITION: WHAT THE PROS ACTUALLY CONSUME

There's a reason you're bonking 60km from home. You're not eating enough on the bike. The current World Tour standard is 80—120g of carbohydrate per hour during hard efforts. Most amateurs are ingesting 20—40g. That's not a small gap — it's a different sport.

Your gut can be trained to tolerate higher carbohydrate intake. Start at 60g/hour and increase by 10g every two weeks. Use a mix of glucose and fructose (2:1 ratio) for optimal absorption. Practice this in training, never in a race or event.

PROTEIN TIMING FOR MASTERS CYCLISTS

New research has shown that protein timing matters more as you age. Muscle protein synthesis — the process by which your body repairs and builds muscle — becomes less responsive to protein intake after

40. You need more protein per meal to trigger the same response, and the timing window around training becomes more critical.

The latest studies support consuming 30—40g of high-quality protein within 60 minutes post-ride, and a further 20—30g before bed. This isn't bodybuilding advice — it's the minimum your body needs to recover from serious training at this age.

BODY COMPOSITION VS SCALE WEIGHT

Let me be really clear about this: your scale weight is almost meaningless as a performance metric. Two riders at 78kg can have completely different body compositions — one at 12% body fat, the other at 22%. They'll perform completely differently on any climb above 5%.

THE RACE WEIGHT MYTH

Every cyclist I know has a race weight in their head. A number they haven't seen since 2015. A number they chase with restriction, self-discipline that borders on punishment, and the quiet shame of stepping on the scale every morning.

Here's what the coaches told me: forget the number. A lean, well-fuelled 80kg rider will outperform a depleted, under-fuelled 76kg version of the same person on every climb above 10 minutes. The power you lose through chronic restriction costs more than the weight you gain through proper fuelling.

YOUR NUTRITION FRAMEWORK: THE FUELLING-FIRST PROTOCOL

- Eat 3 proper meals + 1—2 snacks daily — no meal skipping
- Pre-ride: 1—2g carbs per kg bodyweight, 2—3 hours before
- On-ride: 60—120g carbs/hour (train your gut gradually)
- Post-ride: 30—40g protein within 60 minutes
- Before bed: 20—30g casein or slow-release protein
- Weekly: weigh yourself twice max, track body comp monthly

05

STRENGTH & CONDITIONING

The exercises to avoid — and the five movements that build power after 40

Here's where it gets really interesting. After 40, you're losing muscle mass at roughly 1—2% per year if you're not actively fighting it. That's not just a health stat — it's a performance stat. Less muscle means less power, slower recovery, and higher injury risk. Strength and conditioning isn't optional any more. It's the difference between getting faster and getting hurt.

WHAT TO AVOID: THE HEAVY COMPOUND LIFT TRAP

The fitness industry will tell you to squat heavy, deadlift heavy, bench press heavy. For a cyclist over 40, this is a bad bet. Heavy barbell compound lifts carry a disproportionate injury risk for the benefit they deliver to cycling performance. The connective tissues — tendons, ligaments, cartilage — don't recover like they did at 25. One bad rep under heavy load can take you off the bike for months.

This doesn't mean avoiding resistance training. It means being intelligent about exercise selection. The goal is to build functional power that transfers to the bike, prevent injury, and maintain muscle mass — without the risks that come with maximal loading.

FIVE MOVEMENTS ADAPTED FROM POGAČAR'S PROGRAMME

Dan Lorang's S&C approach for elite cyclists focuses on movement quality, single-leg stability, and controlled resistance. These five exercises are adapted from that philosophy for the amateur cyclist over 40. No barbell required.

1

SINGLE-LEG STEP-UPS

Mimics the pedal stroke under load. Use a bench or step (40—50cm), hold dumbbells at your sides. 3 sets of 8—12 per leg. Builds unilateral power and addresses left-right imbalances.

2

BULGARIAN SPLIT SQUATS

Rear foot elevated, controlled descent, pause at the bottom. 3 sets of 8—10 per leg with moderate dumbbells. Develops hip stability and single-leg strength without spinal compression.

3

NORDIC HAMSTRING CURLS (ASSISTED)

The single best exercise for hamstring injury prevention. Use a band or partner for assistance. 3 sets of 5—8 reps. Eccentric loading builds resilient hamstrings.

4

PALLOF PRESS

Anti-rotation core work that directly transfers to bike stability. 3 sets of 10—12 per side with a resistance band. Builds the core strength that keeps your pelvis stable under power.

5

CALF RAISES (SINGLE-LEG, SLOW ECCENTRIC)

Often neglected, always important. 3 sets of 12—15 per leg with a 3-second lowering phase. Protects the Achilles and builds the ankle stability every cyclist needs.

DAN LORANG

Head of Performance, Red Bull—Bora—Hansgrohe

“The best S&C programme for a cyclist is the one that keeps them on the bike. We focus on movement quality and injury prevention first, strength second. If an exercise carries more risk than it delivers benefit, we remove it. That’s especially true for masters athletes.”

BUILDING POWER WITHOUT ADDING BULK

A common fear: I don’t want to get bulky. Don’t worry — you won’t. Building significant muscle mass requires a caloric surplus and high-volume hypertrophy training. The programme above builds neuromuscular strength — your existing muscles learn to produce more force — without adding mass. Your power goes up. Your weight stays stable. Your watts-per-kilo improves.

INJURY-PROOFING YOUR BODY FOR 20 MORE YEARS

The goal isn’t just to get faster this season. It’s to still be riding seriously at 60. Most cycling injuries in riders over 40 are overuse injuries driven by repetitive motion without adequate off-bike conditioning. Knee pain, lower back issues, hip impingement — these aren’t inevitable consequences of ageing. They’re consequences of not balancing your cycling with the right movement work.

YOUR S&C FRAMEWORK: 12-WEEK ROADMAP

- Weeks 1—4: Learn the movements, light resistance, 2x/week
- Weeks 5—8: Increase resistance progressively, maintain 2x/week
- Weeks 9—12: Consolidate, shift to 1x/week as riding increases
- Always: S&C before hard rides (24h gap), never after
- Track: Can you do more reps at the same weight?

06

RECOVERY

Sleep, stress, HRV, and the adaptation protocol for riders over 40

Here's the craziest part of this whole thing. You don't get fitter during training. You get fitter during recovery. Training is the stimulus. Recovery is when your body actually adapts. And after 40, the recovery equation changes — dramatically — and nobody tells you.

What worked at 30 does not work at 45. Your hormonal recovery profile shifts. Your sleep architecture changes. Your stress tolerance narrows. If you're still training like you're 30, you're not building yourself up. You're breaking yourself down.

SLEEP: THE SINGLE BIGGEST PERFORMANCE LEVER

If you could only change one thing after reading this report, make it sleep. The research is unequivocal: sleep quality has a greater impact on athletic performance than any legal supplement, piece of equipment, or training intervention. And yet it's the one most riders treat as optional.

For masters athletes, the minimum target is 7.5 hours of actual sleep (not time in bed — time asleep). Consistent sleep and wake times matter more than total duration. Late-night screen exposure reduces deep sleep phases by 20—30%, and those deep sleep phases are where growth hormone is released — the hormone responsible for muscular repair and adaptation.

DR DAVID DUNNE

Sports Scientist — Evidence-Based Performance

"Sleep is the most underrated performance tool in endurance sport. A single night of poor sleep reduces power output by 3—5% and increases perceived exertion at the same intensity. Across a week of accumulated sleep debt, you're essentially training in a different body."

STRESS: YOUR BODY CAN'T TELL THE DIFFERENCE

Your body can't tell the difference between work stress and training stress. A bad day at the office and a hard interval session trigger the same cortisol response. If you're running a business, managing a team, dealing with family demands, and then adding 10 hours of structured training on top — your total stress load may be higher than you realise.

This is where intelligent training differs from just training hard. On weeks where life stress is high, training load needs to come down. Not because you're being soft. Because your body is already under load and adding more will push you towards overtraining, not adaptation.

HRV: THE ONE METRIC THAT TELLS YOU WHEN TO PUSH

Heart rate variability (HRV) is the single most useful recovery metric for masters cyclists. It measures the variation in time between heartbeats and gives you a real-time readout of your autonomic nervous system's readiness to perform.

A rising HRV trend means your body is absorbing training well and you can push harder. A declining trend means accumulated fatigue is building up and you need to back off. This is precisely what coaches at the World Tour level monitor daily. You should too.

Measure your HRV every morning, first thing, before you get out of bed. Use the same app and the same device. Look at the 7-day rolling average, not individual readings. When the trend drops below your baseline for three consecutive days, that's your signal to rest.

THE OVERTRAINING TRAP

Overtraining syndrome in masters cyclists is more common than most people realise — and it doesn't announce itself with a dramatic collapse. It creeps in. Your motivation drops. Your power numbers plateau or decline slightly. You catch every cold going. You sleep badly.

The tricky part is that the symptoms of overtraining look identical to the symptoms of not-training-hard-enough. So what do most riders do? They train harder. Which makes it worse.

PROFESSOR STEPHEN SEILER

Exercise Physiologist — Pioneer of Polarised Training Research

"The masters athlete who gets this right — who treats recovery as a training tool rather than an absence of training — consistently outperforms the one who just trains hard. After 40, your ability to recover becomes your most important performance variable."

THE RECOVERY WEEK: YOUR SECRET WEAPON

Every third week should be a recovery week. Not a week off — a structured reduction. Drop volume by 30—40%. Remove all high-intensity sessions. Keep the Zone 2 work but shorten it. This isn't laziness. This is when the adaptation you've been chasing for the past two weeks actually happens.

Most riders skip recovery weeks because they feel good. They're finally hitting their stride and the idea of backing off feels counterproductive. Here's the thing: the adaptation happens when you rest, not when you train. If you never rest properly, you never fully absorb the work you've done. Two steps forward, one step back — that's the rhythm of getting faster.

Track how you feel at the end of each recovery week. If you're doing it right, the first hard session of the next block should feel noticeably sharper. Your power will be higher at the same RPE. Your legs will respond faster. That's the signal that the system is working.

YOUR RECOVERY FRAMEWORK: THE ADAPTATION PROTOCOL

- Sleep: 7.5+ hrs actual sleep, consistent times, screens off 60 min before
- HRV: Measure every morning, track 7-day rolling average, act on trends
- Stress audit: Rate non-training stress weekly (1—10), adjust accordingly
- Rest days: Min 1 complete rest day per week, ideally 2
- Recovery weeks: Every 3rd week, reduce volume/intensity by 30—40%
- Nutrition: Don't under-fuel on rest days — your body needs resources

07

COMMUNITY LE MÉTIER

The craft of being a cyclist, and why it matters as much as your FTP

The French have a word for it: *le métier*. The craft. The trade. The unwritten knowledge of how to be a cyclist — not just how to ride a bike, but how to belong to the sport. How to read a bunch. How to ride through. How to suffer well. How to show up, day after day, for something bigger than your own numbers.

This is the pillar most riders overlook. And it's the one that separates the cyclist who plateaus from the cyclist who keeps getting better.

WHY THE LONE WOLF ALWAYS HITS A CEILING

There's real data behind this. Riders who train with a structured group — not just a social club ride, but a group with shared goals and accountability — consistently outperform lone wolves over 12-month periods. The mechanisms are both physiological and psychological.

Physiologically, group riding exposes you to variable pacing, race-like surges, and efforts you'd never do on your own. It trains your anaerobic system in ways that solo Zone 2 riding cannot. Psychologically, accountability removes the option of cutting a session short because I'm not feeling it. Someone is waiting for you. That matters.

"The best riders I've coached over 40 all have one thing in common: they're part of something. Not a platform. Not an app. A group of people who expect them to show up and who notice when they don't."

— Professor Stephen Seiler

WHAT RIDING WITH BETTER CYCLISTS DOES TO YOU

When I had Lachlan Morton on the podcast, he talked about something most people don't consider: the way being surrounded by better riders changes your internal ceiling. You stop thinking of certain efforts as impossible. You start seeing them as normal. Your reference point shifts, and with it, your performance.

This isn't motivational fluff. There's a well-documented social facilitation effect in endurance sport. Time trial performance improves by 1—3% simply by having someone riding alongside you at a similar level. Over a season, those marginal gains compound.

THE NOT DONE YET EFFECT

Inside the Not Done Yet community, 113 serious cyclists are applying all five of these pillars together. They're following Vekta-powered training plans built on the polarised model. They're using the fuelling-first nutrition protocol. They're running the S&C roadmap. They're tracking their recovery with HRV and structured rest weeks.

The results speak for themselves: members going from Cat 3 to Cat 1. Body fat dropping from 20% to 7%. Women's National Series results. Power numbers that riders didn't think were possible any more.

"I went from 84kg and an average wattage I'm embarrassed to mention, to a body fat percentage I haven't had since university and power numbers I didn't think were possible any more."

— Chris O'Connor, Not Done Yet Member

TRAINING WITH OTHERS: THE SCIENCE OF SOCIAL FACILITATION

The research on social facilitation in endurance sport is striking. A 2019 meta-analysis found that time trial performance improves by 1—3% simply by having someone riding alongside you at a similar level. That's not a motivational estimate — it's a measured physiological effect. Your pain tolerance increases. Your RPE at the same power output decreases. You literally become a different athlete when someone is next to you.

Over a season, those marginal gains compound. The rider who does one hard group ride per week gets 40+ exposures to race-like intensity that the solo rider never experiences. By the time both riders pin a number on, the group rider has accumulated a massive advantage in pacing awareness, bunch skills, and the ability to dig deep when it hurts.

This is why the Not Done Yet community runs structured group sessions — not just social rides. There's a difference between riding with people and training with people. The former is fun. The latter is transformative.

RIDING THROUGH

There's a phrase we use at Roadman: *riding through*. Always riding through, never sitting up, never coasting. Being smart, working hard, making an effort, contributing to the group. That's the ethos. It's not about winning the race. It's about being part of something — a global cycling community.

Every rider in the Not Done Yet community carries that ethos. We don't have all the answers, but we ask all the questions. We share the failures alongside the wins. We hold each other accountable because that's what riding through means — you don't sit up when it gets hard. You keep pedalling.

YOUR COMMUNITY FRAMEWORK: BUILDING LE MÉTIER

- Find riders who are slightly better than you — ride with them
- Join a structured community with shared goals and accountability
- Share your training openly — visibility creates commitment
- Show up consistently, even on weeks when you don't feel it
- Contribute to others' progress — coaching up reinforces your own

08

YOUR NEXT STEP

What Not Done Yet looks like from the inside

08

YOUR NEXT STEP

You've read the system. You know what the coaches prescribe. You've seen the frameworks.

Now you have a choice. You can go back to the cycling internet, piece together conflicting advice from Reddit threads and YouTube comments, and keep guessing. Or you can plug into the system.

Not Done Yet is where serious cyclists over 35 apply all five pillars together, with structured coaching, live support, and a community that expects you to show up. It's not a beginners' group. It's not a ghost town. It's 113 riders who are proving that the best days aren't behind them.

WHAT YOU GET INSIDE NOT DONE YET

- Weekly live coaching calls with Anthony Walsh
- Vekta-powered training plans built on the polarised model
- The full S&C roadmap (12-week programme, video demonstrations)
- Nutrition frameworks and fuelling protocols
- Recovery tracking tools and guidance
- Private community of serious, accountable cyclists
- Masterclasses from expert guests
- Direct access to ask questions and get answers

JOIN NOT DONE YET

<https://www.skool.com/roadmancycling>

£195 per month

This isn't a Netflix subscription you forget about. It's a system that works when you work it. The riders inside will tell you: the investment pays for itself in the first month.

WHO IT'S NOT FOR

If you're looking for a quick fix, a magic workout, or a 6-week transformation programme, this isn't it. The system works because it's comprehensive, consistent, and long-term. If you want someone to tell you that one weird trick will add 50 watts, the cycling internet has plenty of that. We don't.

You're not done yet.
